Latent transition model

Associative latent transition model

Empirical illustration - Methods

Empirical illustration - Results

Selected ALTA estimates

Conclusions

- Focus on unobservable groups or categories in the population.
- How does change among discrete states proceed over time?
- How well are states measured?
- Is change comparable between two groups (e.g., treatment and control)?
- How are two changing categorical variables associated?

Conclusions

$$P(\mathbf{W}) = \sum_{c=1}^C \gamma_c \left(\prod_{j=1}^q \prod_{k=1}^{r_j} \rho_{jk|c}^{I(w_j=k)} \right)$$

where

- \mathbf{W} is a response pattern;
- γ_c is the proportion of the population in latent class c ;
- $\rho_{jk|c}^{I(w_j=k)}$ is the probability of response k to item j for latent class c .
- $I(\cdot)$ is the indicator function, here used to select the appropriate response probabilities.

I will abbreviate latent class as LC.

Associative latent transition model

Empirical illustration - Methods

Empirical illustration - Results

Selected ALTA estimates

Conclusions

- Typically use G^2 or Pearson's X^2 .
- But, fit assessment is difficult due to sparse tables.
 - Sparse means a low n relative to the number of cells in the observed data contingency table.
 - Sparseness reduces the expectation of the test statistic.
- Typical practice with sparse data:
 - Ideally G^2 lower than df
 - Interpretable solution
- Model comparisons (i.e., nested comparisons) perform better than absolute fit tests with sparse data

Selected ALTA estimates

Conclusions

Interested in two latent classes at two time points.

Could fit a four class LC model (2 classes \times 2 times):

LC 1	LC 1	LC 2	LC 2
LC 1	LC 2	LC 1	LC 2

Diagram of LTA for two times

Instead, one can model the starting point and then change between time points.

Transition probabilities are row conditional.

Same number of estimates in these two approaches, hence reparameterization.

Conclusions

Three Yes/No items measuring recent tobacco use:

- Have you ever tried cigarette smoking, even just 1 or 2 puffs?
- Have you smoked cigarettes on any of the last 30 days?
- Have you ever smoked cigarettes regularly (at least 1 cigarette every day for 30 days)?

Three Yes/No items measuring recent alcohol use:

- Have you had a drink of beer, wine, or liquor—not just a sip or a taste of someone else’s drink—more than 2 or 3 times in your life?
- Have you drunk alcohol in the past 12 months?
- Have you ever been drunk or drunk 5 or more drinks in a row in the past 12 months?

Items

▷ Analyses

Empirical illustration - Results

Selected ALTA estimates

Conclusions

- Fit single LTA models first:
 - Choose a number of LC's;
 - Examine measurement structure.
- Fit multiple sets of start values to base ALTA model to assess identification (i.e., multi-modality).
- Fit ALTA model corresponding to various patterns of association between tobacco and alcohol classes.

Selected ALTA estimates

Conclusions

Conclusions

▷ Limitations

- Big models, a lot of parameters;
- Shares difficulties in assessing fit with other large latent class models;
- Current implementation doesn't provide standard errors.

Not yet clear what the bounds are of this model:

- How many times?
- How many classes?
- How many items?
